

# Integrity and Agricultural Landowner Behavior in Afforestation for Carbon Sequestration as part of a Carbon Pricing Program

David Haim & Eric M. White  
EMAGG workshop, ERS, August 8th 2013

# Introduction – Carbon Markets

- ▶ Regional markets in the US
  - Regional Greenhouse Gas Initiative (RGGI)
  - Cap-and-trade program in California
- ▶ European Union Emissions Trading System
- ▶ Carbon price projections: rise to \$20–\$80 per CO<sub>2</sub>e by 2030 with further increases by 2050 (IPCC, 2007)
- ▶ Agricultural and forest sectors potential to serve as carbon offset providers
  - American Clean Energy and Security Act
  - Control land use emissions and increase land use sinks (Reilly & Asadoorian, 2007)

## Objective

Quantify leakage behavior and investigate permanence issues of agricultural land afforestation under simulated national and region-specific carbon offset markets

## Agricultural Afforestation Importance

Agricultural sector activities for GHG mitigation include:

- ▶ Conversion of cropland to grasses
- ▶ Adoption of conservation tillage practices
- ▶ Change in fertilizer regimes
- ▶ Manure management
- ▶ Afforestation

## Agricultural Afforestation Integrity

Intensification within the agricultural sector:

- ▶ Reduction in idle agricultural land
- ▶ Adoption of more intense management practices
- ▶ Conversion of pasture to cropland

Leakage:

- ▶ Emissions displacement in time and space outside the afforestation program's boundaries
- ▶ Intensification of agricultural production within the afforestation program's boundaries

Previous leakage estimates: Murray et al, (2004)

## Approach

- ▶ Extend and apply FASOM-GHG to model agricultural afforestation
- ▶ Complete regionally-explicit model runs for the conterminous U.S.
- ▶ Run the model for the period between 2010 and 2080
- ▶ Examine carbon prices of \$30 & \$50 per tonne CO<sub>2</sub>e
- ▶ Include baseline Renewable Fuels Standard

## FASOM-GHG

- ▶ An equilibrium linked model of U.S. agricultural and forest sectors
- ▶ Utilizes a dynamic optimization approach to simulate markets for agricultural and forest products
- ▶ perfect foresight regarding future demand, yields, technologies, and prices
- ▶ Regionally-explicit

## FASOM-GHG

- ▶ Commodity and factor prices are endogenous
- ▶ Land conversion to develop uses
- ▶ Tracks a variety of agricultural and forest resource conditions and management actions
- ▶ International trade in both agricultural and forest products
- ▶ Includes GHG accounting and a bioenergy sector

# GHG Accounting

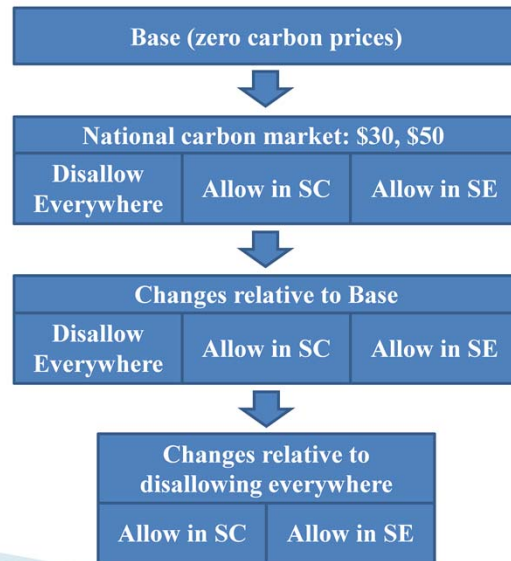

Land-based GHG accounting in agricultural and forest sectors from:

- ▶ Carbon in agricultural and forest biomass and soils
- ▶ Carbon change due to movement of land (afforestation/deforestation) between agriculture and forest
- ▶ Emissions from agricultural and forest production activities
- ▶ Emissions from livestock
- ▶ Carbon in wood products

## FASOM-GHG

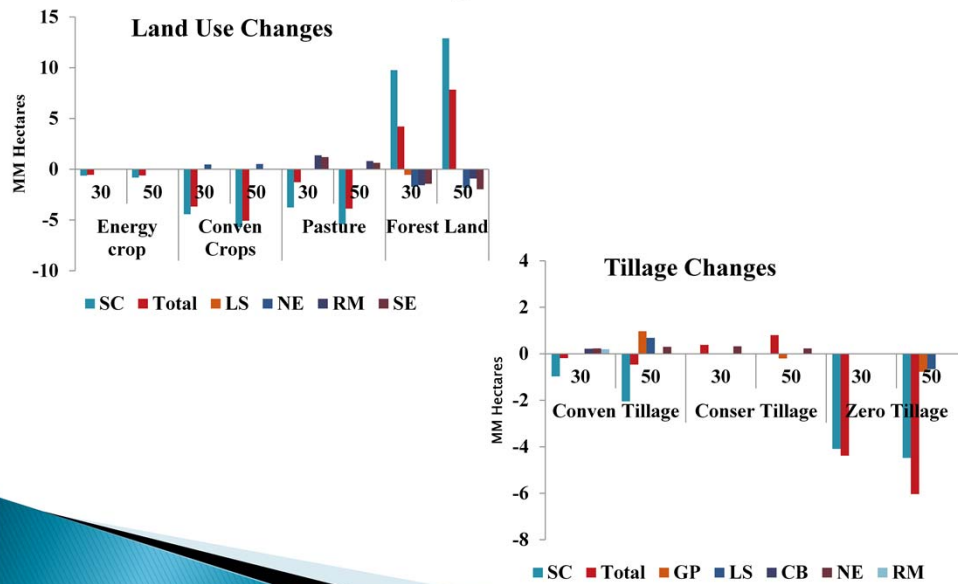

## Simulations – Leakage

## Land use and tillage changes – only SC (short-term)

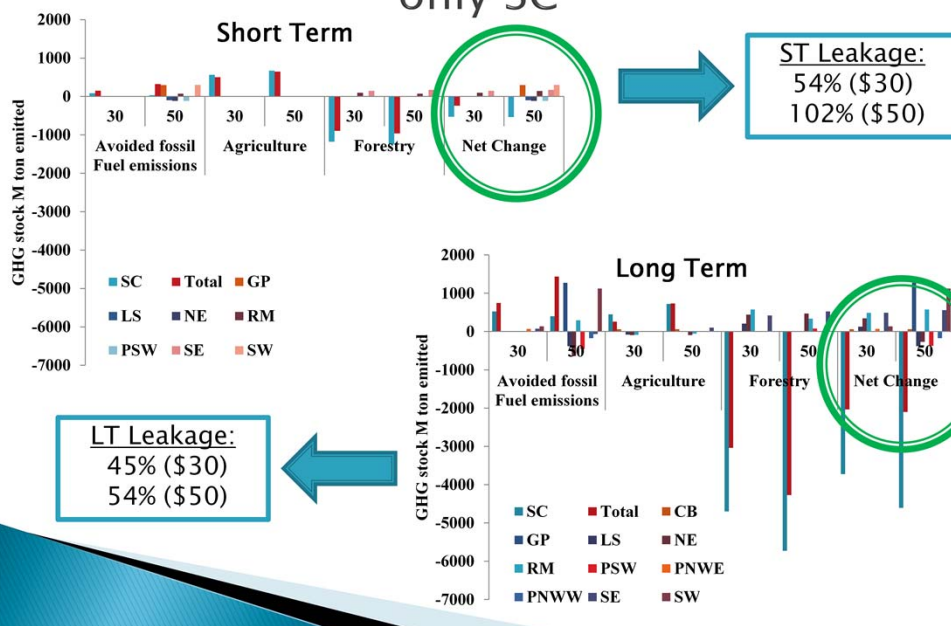

## Land use and tillage changes – only SC (long-term)

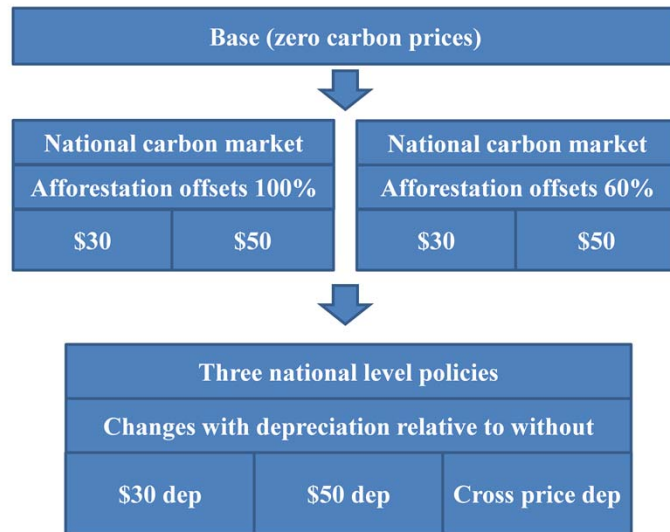

## Afforestation – only SC (2010–2055)

# Changes in stocks of GHG emissions – only SC

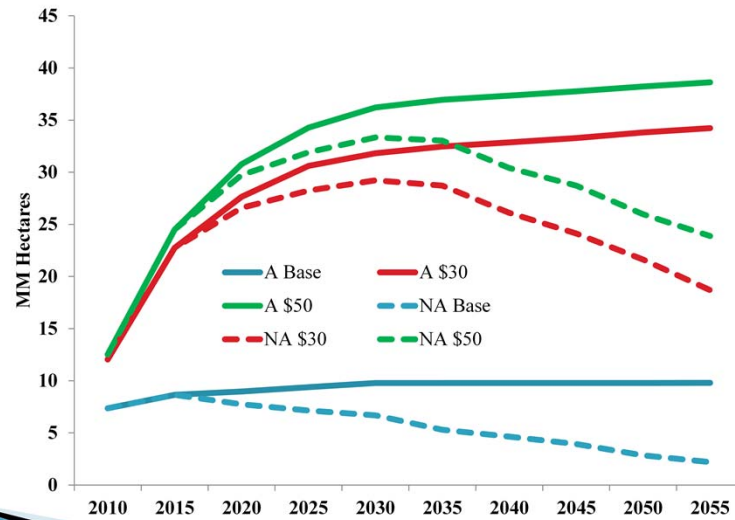

## Simulations – Permanence

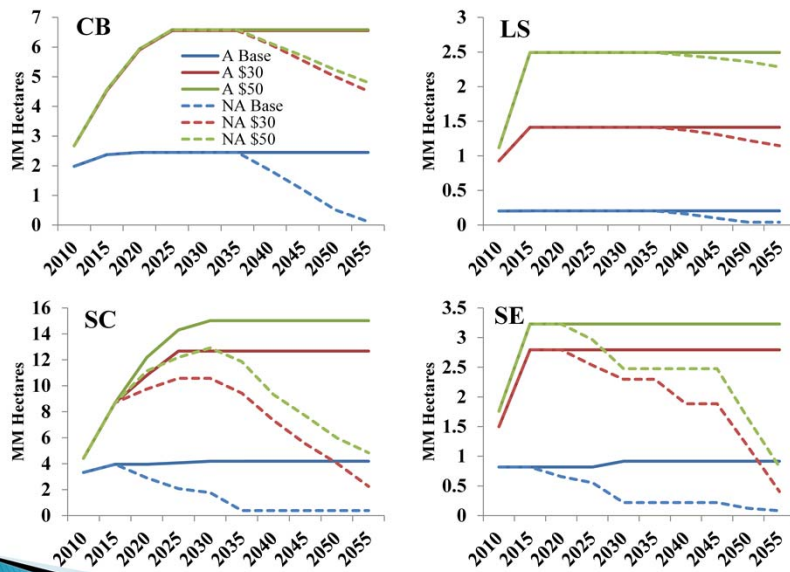

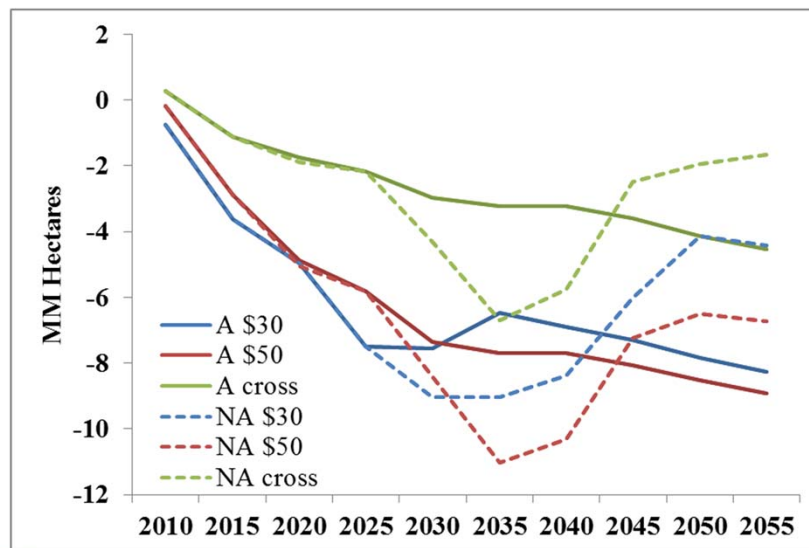

# Cumulative Afforestation and Net Afforestation Levels: Unmodified Carbon Market (National)

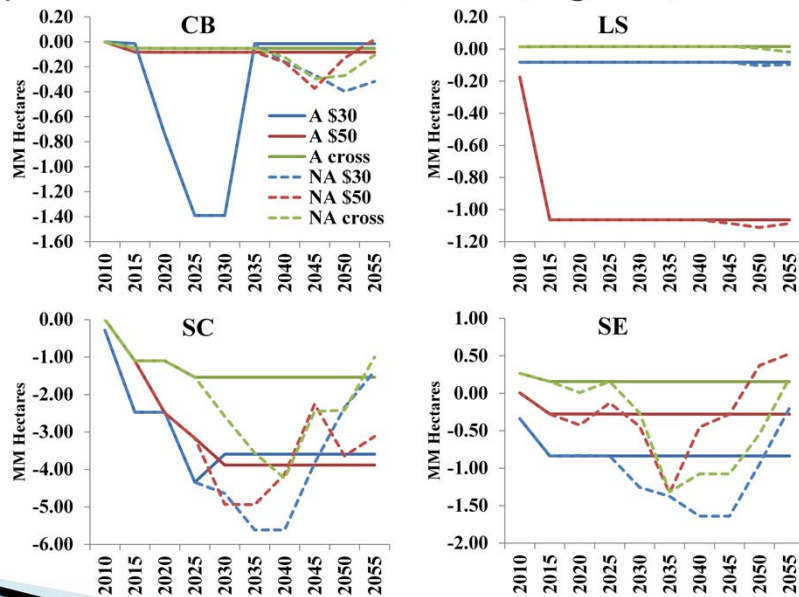

## Cumulative Afforestation And Net Afforestation Levels: Unmodified Carbon Market (Regional)

# Changes in Cumulative Afforestation and Net Afforestation: Depreciated Afforestation Offsets (National)

## Changes in Cumulative Afforestation and Net Afforestation: Depreciated Afforestation Offsets (Regional)

## Discussion (leakage)

- ▶ Net gains are much greater in the long-term
- ▶ Intensified agricultural production in the GP and LS regions in the short and long terms
- ▶ Could result in as much as an additional 400 million tonnes annual-average GHG stored. Equals to 6% of US GHG emissions in 2010 (EPA, 2012)
- ▶ Leakage from the regional SC allowance program is in the range of 45–55% in the long term but could be as high as 100% in the short term.
- ▶ For the SE regional allowance program: land use changes are smaller and leakage is always greater than 100%

## Discussion (permanence)

- ▶ Most of the afforested area in the Midwest regions remains unharvested in the long term. The opposite is true for the Southern regions
- ▶ A permanence value reduction promotes the harvesting of afforested stands in the Southern regions
- ▶ Mixed results in terms of carbon price levels

THANK YOU
