# Conserving Spatially Explicit Benefits in Ecosystem Service Markets

**Jacob Fooks, University of Delaware**

Co-Authors:

Joshua Duke, University of Delaware

Daniel Hellerstein, USDA-Economic Research Service

Nathaniel Higgins, USDA-Economic Research Service

Loretta Lynch, University of Maryland

Kent Messer, University of Delaware

# Conservation Auctions

---

- Public-good, ecosystem services (like CRP, EQIP, agricultural land preservation, etc.)
    - Conservation produces a positive externality: The “Conservation Externality”
    - “Reverse” auctions
  - Presumably, auctions decrease rent extraction
    - Budget constraint, enables maximum public goods
  - Information asymmetry prevents “efficient” auctions
    - Sellers secure premiums above reservation rents
    - Kirwan et al (2005) estimate premiums of 10-40% of CRPs rental payouts
  - Recent literature explores auction performance
-

# Agglomeration

---

- Extensive work on spatial interdependency and benefit nonlinearity
  - Corridors, green infrastructure, thresholds, shape factor, boundaries
  - Targeting
  - Williams, ReVelle, and Levin (2005); Malcolm and ReVelle (2002)
- Agglomeration Bonus - Parkhurst, Shogren, etc. (2002, 2007, 2008)
  - Adjacent landowners along a river...
  - Selectively pay bonuses to incentivize certain outcomes
  - Spatially explicit coordination games and experiments
- All this literatures suggests an additional positive externality associated with proximity
  - The “Spatial Externality”

# Framing Spatial Literature

Supply	Demand	Buyer Spatial Preferences in Selection	No Buyer Spatial Preferences in Selection
	Bonuses Paid	???	Agglomeration literature
	No Bonuses Paid	Targeting literature	Most programs in real world

“Buyer” refers to a social planner

Buyer may have preferences for the spatial externality

“Bonuses” are additional premiums paid to landowners for the spatial externality

# Policy Hypotheses

- Which combination of institutions produce the greatest social welfare?
  - Political considerations tend to spread funds more evenly (IV)
  - Might (I) reflect optimal internalization? But what about collective rent seeking from bonuses? Individual strategic rent seeking?
- Will agricultural landowners behave differently from student subjects in the lab? Evidence from farmer experiments
- Can an optimal bonus be set?

<b>Supply</b>	<b>Demand</b>	<b>Buyer Spatial Preferences in Selection</b>	<b>No Buyer Spatial Preferences in Selection</b>
	<b>Bonuses Paid</b>	I	II
	<b>No Bonuses Paid</b>	III	IV

# Experiment Design

- Key Elements:

Subjects	120 Subjects (96 Undergraduates, 24 Farmers)
Session Setup	3 Rooms; 12 Subjects, 4 per room
Time Structure	9 Enrollment Periods, 3-6 rounds each
Parcel Distribution	3 per subject, grouped by room
Treatments	Within: Bonuses Between: Communication, Spatial Weighting
Average Earnings	\$30 for Undergraduates, \$75 for Landowners
Time	2.5 Hours

# Experiment Design

- Each subject acts as the owner of three parcels of land.
- In each round, subjects decide between retaining parcels in their current use, or entering an auction to try to “sell” the parcel to the administrator.
- Subjects know the distributions of returns and budgets, and are told the current budget during each round.
- In each new enrollment period the world resets, and subjects receive new parcels
- Opportunity costs are heterogeneous between rooms; high, medium, and low cost rooms – similar to real life situations.

1000s			Room 1
1	2	3	
4	5	6	
7	8	9	
10	11	12	

2000s			Room 2
1	2	3

7	8	9	
10	11	12	

# Experiment Design

- The buyer decision criteria may be effected by the
- Connectivity is calculated by the “walkthrough” length of a network.
- Networks are defined as groups of parcels that share adjacent sides.
- Connection across diagonals (“rook” connectivity) or in different rooms not included.
- Networks are cumulative over rounds within an enrollment period.

Scenario A				Scenario B				Scenario C			
Network Sizes: 4, 3, 1				Network Sizes: 5, 3				Network Sizes: 7, 1			
Buyer Value: 30.6				Buyer Value: 41.6				Buyer Value: 67.2			
1	2	3		1	2	3		1	2	3	
2	3	4		2	3	4		2	3	4	
3	4	1		3	4	1		3	4	1	
4	1	2		4	1	2		4	1	2	
5	6	7		5	6	7		5	6	7	
6	7	8		6	7	8		6	7	8	
7	8	5		7	8	5		7	8	5	
8	5	6		8	5	6		8	5	6	

# Experiment Design

- Bonuses are paid on a one time basis to all members of a network of size 2 or more for each parcel that enters the network.
  - Bonus payments are \$50,000 per parcel in the network.
  - When a new parcel enters an existing network, all current members of the network receive a “top-up” bonus.

Scenario A				Scenario B				Scenario C			
Network Sizes: 4, 3, 1				Network Sizes: 5, 3				Network Sizes: 7, 1			
Buyer Value: 30.6				Buyer Value: 41.6				Buyer Value: 67.2			
1	2	3		1	2	3		1	2	3	
2	3	4		2	3	4		2	3	4	
3	4	1		3	4	1		3	4	1	
4	1	2		4	1	2		4	1	2

7	8	5		7	8	5		7	8	5	
8	5	6		8	5	6		8	5	6	

# Experiment Design

Maximized a grading function over all possible network configurations of submitted parcel offers,  $B^*$ :

$$\begin{aligned} \max_{X \in B^*} G &= \sum_{x_n \in X} (x_n + \beta x_n^2) \\ \text{s.t. } \sum_{i,n} b_i + \gamma x_n &\leq C \end{aligned}$$

where:

$X$  is a configuration of networks

$x_n$  is the length of an individual network,  $n$

$b_i$  is the offer submitted for parcel  $i$

$C$  is the total budget for the conservation program

$\beta$  is a contiguity preference parameter

$\gamma$  is a bonus payment rate parameter

Solved using an evolutionary algorithm in Risk Solver Platform

# Results

# Results

The figure displays a 3x6 grid of heatmaps, where the columns represent Round 1 through Round 6, and the rows represent three different baselines. A color bar on the right indicates the scale of the results, ranging from 0 (light green) to 1 (dark green). The top row shows a relatively stable, dark green pattern across all rounds. The middle row shows a transition from light green in Round 1 to a more uniform dark green by Round 6. The bottom row shows a transition from light green in Round 1 to a more uniform dark green by Round 6.

	Round 1	Round 2	Round 3	Round 4	Round 5	Round 6

## Primary Conclusions

---

- If spatial externalities exist, a social planner can improve outcomes by specifically targeting them.
    - Will select sets closer aligned with social values
    - Can also increase strategic waiting
  - Spatial targeted bonuses have mixed effects.
    - Induce entry of desirable parcels into the market
    - Very budget intensive (in this case largely dominated – optimal bonus?)
  - Bonuses work best in conjunction with a spatial targeting mechanism
    - There is a synchronicity between the two approaches; bonuses help correct for strategic waiting, while targeting is able to optimally take advantage of larger offer pool.
  - Field experiments with farmers show similar, slightly stronger dynamics.
-
