USDA/NFP/CFTC Workshop on Carbon Market

Design: Issues and Opportunities

Washington DC, January 31 – February 1 2011

Schulich
School of Business

Background and motivation

- Carbon emissions are a new traded financial instrument. So, a natural question to ask is:

How do carbon prices interact with other financial variables like oil prices, stock prices and interest rates?

Past research

- Recent papers on EU-ETS include:
- E. Alberola, J. Chevallier, B. Cheze, 2008;
- Mansanet-Bataller, M., Pardo, A., Valor, E., 2007;
- E. Benz, S. Truck, 2009;
- J. Chevallier, 2009, 2011;
- E. Alberola, J. Chevallier, B. Cheze, 2008;
- M. Mansanet-Bataller, J. Chevallier, M. Herve-Mignucci, E. Alberola, 2010;

Past research

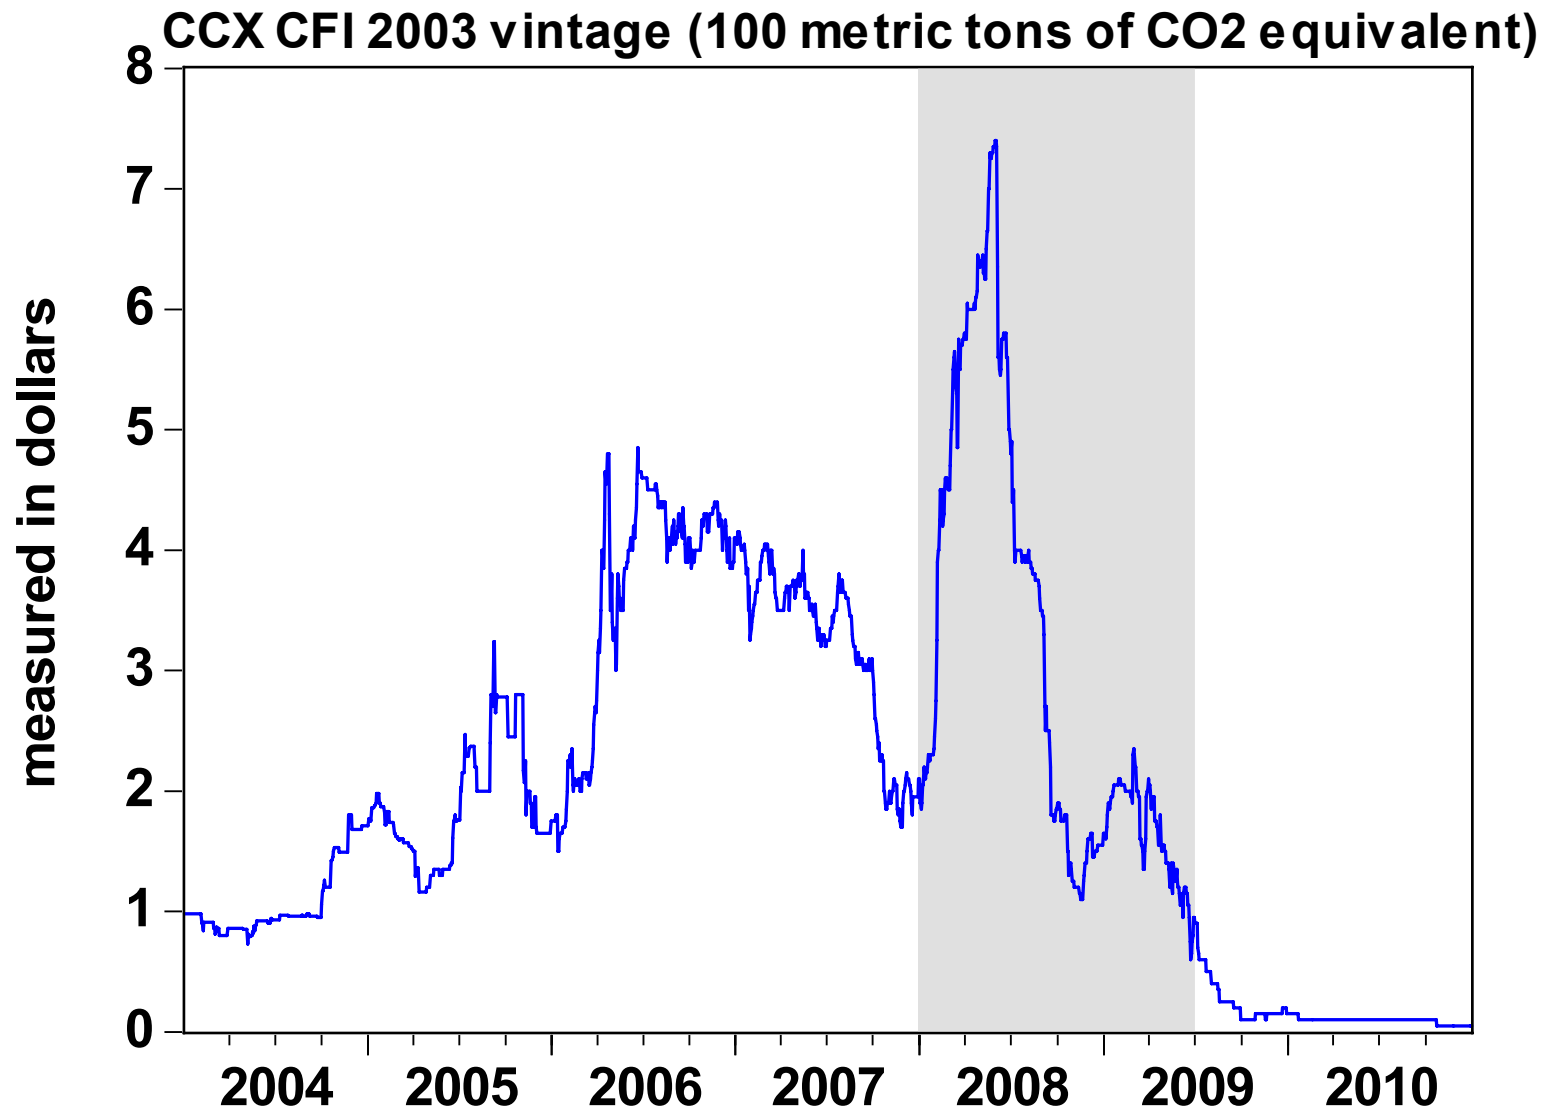

- Recent paper on CCX is:
- H.S. Kim and W.W. Koo, 2010
- Recent paper on Australia is:
- J. Chevallier, 2010

Objective

- Conduct a multivariable analysis of the dynamic interactions between carbon prices, oil prices, stock prices and interest rates.

Data

- Data on carbon prices (CCX CFI vintage 2003, 100 metric tons of CO₂ equivalent), oil prices (WTI futures prices), stock prices (SP500, ECO), and interest rates (3 month T bill).
- On the CCX, earlier dated vintages may be delivered against later vintage trades.

Data

- The Great Recession has caused a structural break so estimation period is, 1/02/2004 7/31/2008 (before the Lehman's bankruptcy).
- CCX trading volume was zero from February 2010 onwards and trading has now ceased.
- Intrade currently predicts a 5% (20%) probability of a cap and trade system being established before midnight Dec 31, 2011 (2013).

Summary statistics (daily data)

| | %ΔCFI2003 | %ΔWTI | %ΔSP500 | %ΔECO | T bill |
|-------------------------|------------------------------------|--------------------------------|----------------------------------|--------------------------------|---------------|
| Mean | 0.12 | 0.11 | 0.01 | 0.02 | 3.28 |
| Median | 0.00 | 0.11 | 0.05 | 0.04 | 3.41 |
| Maximum | 18.90 | 8.08 | 4.15 | 6.11 | 5.19 |
| Minimum | -25.49 | -7.70 | -3.53 | -6.88 | 0.61 |
| Std. Dev. | 3.61 | 2.01 | 0.84 | 1.62 | 1.46 |
| Skewness | -0.29 | 0.02 | -0.20 | -0.19 | -0.19 |
| Kurtosis | 14.68 | 3.41 | 5.38 | 4.15 | 1.58 |
| Jarque- Bera | 6800.77 | 8.28 | 289.86 | 72.57 | 107.67 |
| Probability | 0.00 | 0.02 | 0.00 | 0.00 | 0.00 |
| Sharpe | 0.03 | 0.01 | 0.00 | 0.05 | |
| Nobs | 1194 | 1194 | 1194 | 1194 | 1194 |

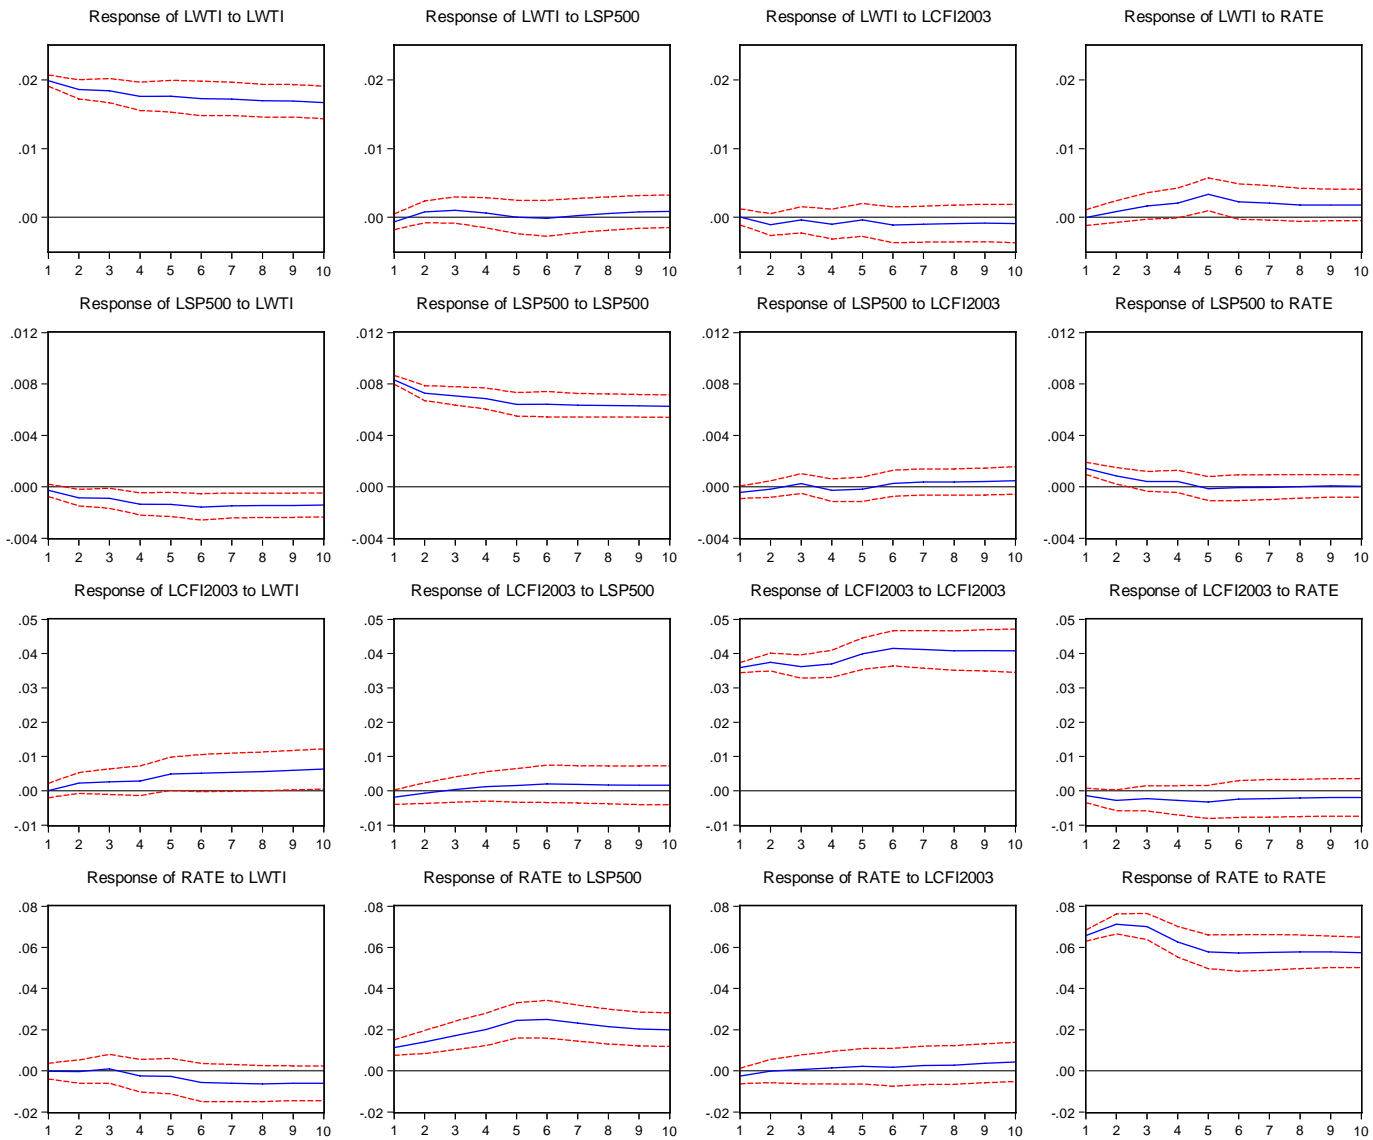

Empirical Approach

- Toda and Yamamoto (1995) Vector Autoregression (VAR) approach.
- Estimate the VAR in levels, use a standard lag length selection criteria to select appropriate lag length, and add additional lags if data contain unit roots or are cointegrated.

VARs

- One VAR for carbon, oil, SP500, interest rate.
- Another VAR for carbon, oil, ECO, interest rate.
- TY approach. LR selects 5 lags (plus one more lag for possible unit roots), so estimate VARs with 6 lags. AR roots less than unity (satisfies stability condition).

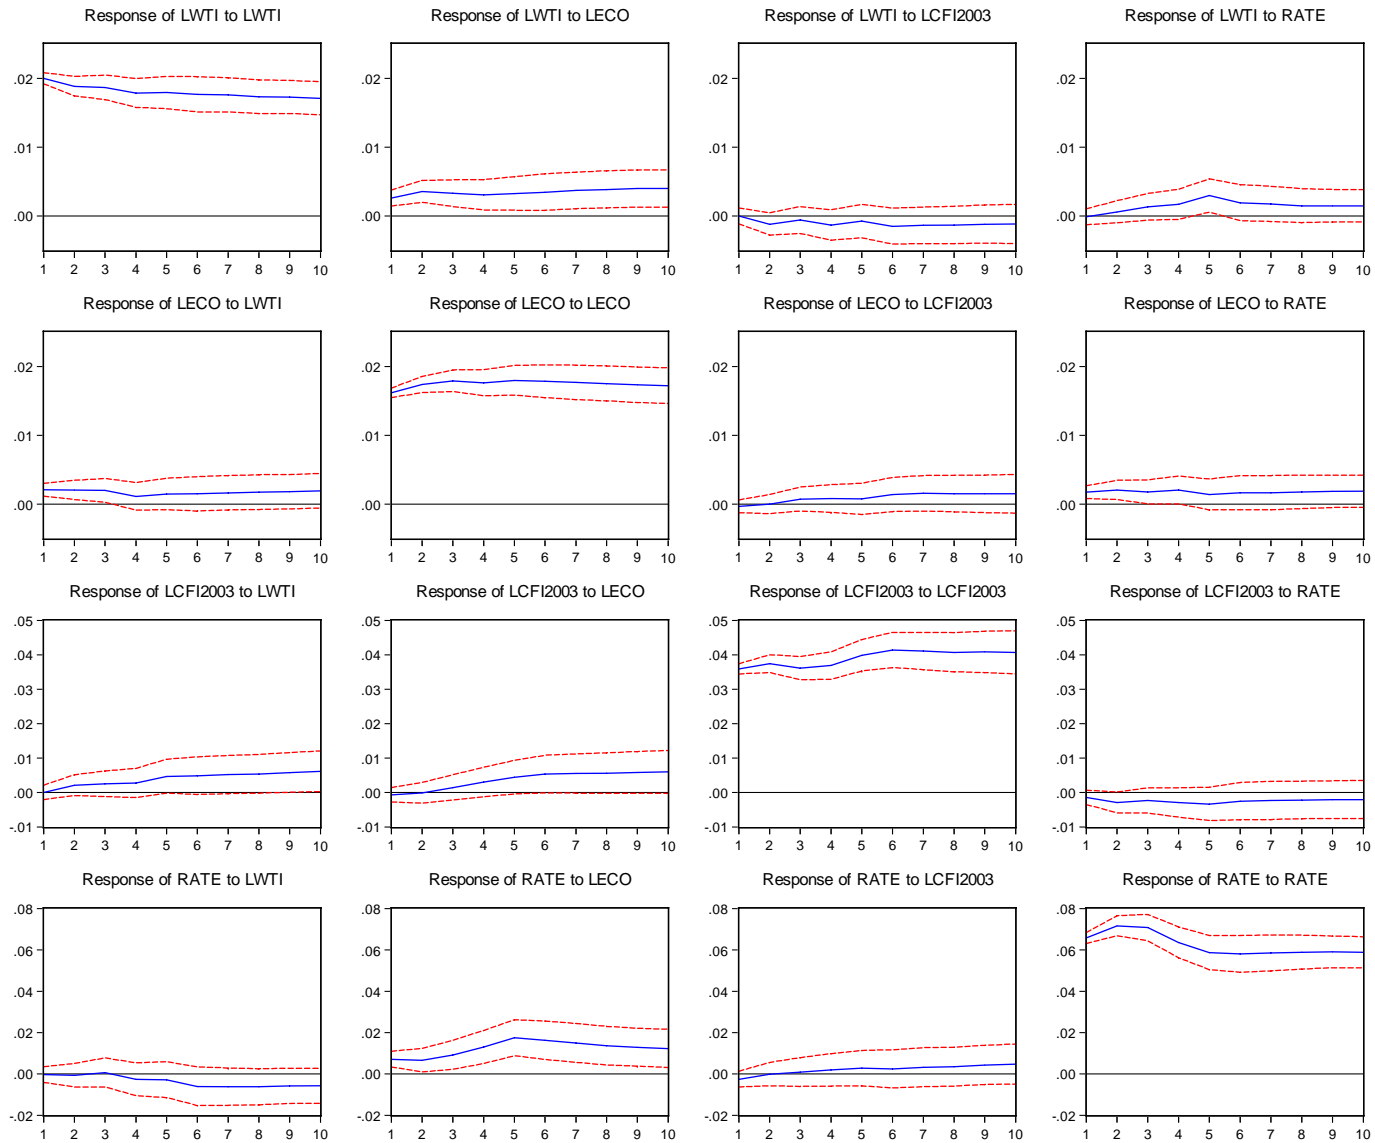

Response to Generalized One S.D. Innovations ± 2 S.E.

Response of LCFI2003 to Generalized One S.D. LWTI Innovation

Response to Generalized One S.D. Innovations ± 2 S.E.

Results

- Carbon prices increase in response to a one standard deviation shock to oil prices. Higher oil prices are associated with a growing economy and more emissions.

Results

- The other financial variables do not respond statistically to shocks to carbon prices.
- A one standard deviation shock to oil prices reduces the S&P 500. This is in agreement with a large literature showing stock prices respond negatively to oil price increases (Sadorsky, 2008).

Results

- A one standard deviation shock to oil prices increases ECO. This is in agreement with the idea that higher oil prices encourage investment in alternative energy. After 4 days, however, the impulse is statistically insignificant.

Results on volatility

- Use a MGARCH(1,1) model (Diagonal vech multivariate GARCH model) to estimate the conditional variances and covariances.

Implications

- These results help to understand price patterns of carbon.
- Oil prices are possibly useful for forecasting carbon prices.
- Hedging opportunities.
- Portfolio diversification (think of carbon as a traded commodity).
- Green portfolios and socially responsible investing.

Caveats

- Carbon emissions prices depend upon a vibrant market for carbon emissions. A vibrant market can come about because either
 1. Companies voluntarily join (CCX)
 2. Carbon emissions are regulated (EU-ETS)

Caveats

- Joining a voluntary market is useful for learning purposes but ultimately a regulated carbon market is more powerful than a voluntary market so the future of carbon markets depends upon carbon regulation.
